Mathematically, various ways exist to represent applied general equilibrium (AGE) models, according to Ginsburgh and Keyzer¹. To identify the optimal solution towards greater sustainability and enable the efficient allocation of resources in the economy, we used the welfare format of the AGE models for our analysis. In the supplementary information, we specified the model for our study by explicitly considering producers, consumers, production goods, consumption goods, and intermediate goods. Subsequently, we presented the calibration of our model. Finally, we provided supplementary figures and tables, along with the sectoral aggregation scheme, social accounting matrices, and emissions data for all the regions in our study.

Supplementary Methods

Objective function

The objective function "social welfare (W)" is the weighted sum of the log utility (U_i) of all consumers, according to Zhu and Van Ierland².

$$W = \max \sum_i \alpha_i \log U_i \quad (1)$$

where α_i is the Negishi weight of the representative consumer in each region i (i =China and its main food and feed trading partners (MTP, including Brazil, United States, and Canada)).

Utility function

In our model, the consumer's utility depends on the consumption of rival goods. The utility function is a Cobb-Douglas (C-D) function describing the behaviour of a representative consumer (household to maximise its utility subject to budget constraints) consuming rival goods. The utility function of the consumer in region i is written as:

$$U_i = \prod_s C_{i,s}^{\beta_{i,s}} \quad (2)$$

where consumption goods s refers to cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, sugar crops, other non-food crops, monogastric livestock, ruminant livestock, processed food, and non-food. $C_{i,s}$ is the consumption of the rival good in region i . $\beta_{i,s}$ is the elasticity of utility concerning the consumption of rival good s in region i , i.e., the expenditure share of consumption good s in consumption of rival goods in region i , and $\sum_s \beta_{i,s} = 1$.

Production function

We present the production functions of seventeen producers, namely, cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, sugar crops, other non-food crops, monogastric livestock, ruminant livestock, compound feed, cereal brans, alcoholic pulps, oil cakes, processed food, nitrogen fertiliser, phosphorus fertiliser, and non-food.

The production function of producer j in region i is specified as:

$$Y_{i,j} = A_{i,j} [(KL_{i,j})^{\eta_{1i,j}} (LB_{i,j})^{\eta_{2i,j}} (LD1_{i,j})^{\eta_{3i,j}} (LD2_{i,j})^{\eta_{4i,j}} (NFE_{i,j})^{\eta_{5i,j}} (PFE_{i,j})^{\eta_{6i,j}} \\ (CER_{i,j})^{\eta_{7i,j}} (OSD_{i,j})^{\eta_{8i,j}} (VF_{i,j})^{\eta_{9i,j}} (RT_{i,j})^{\eta_{10i,j}} (SGR_{i,j})^{\eta_{11i,j}} (OTC_{i,j})^{\eta_{12i,j}} \\ (COF_{i,j})^{\eta_{13i,j}} (BRAN_{i,j})^{\eta_{14i,j}} (PULP_{i,j})^{\eta_{15i,j}} (CAKE_{i,j})^{\eta_{16i,j}}]^{1-\xi_{i,j}}$$

$$\begin{aligned}
& [(CERW_{i,j})^{\delta_{1i,j}} (OSDW_{i,j})^{\delta_{2i,j}} (VFW_{i,j})^{\delta_{3i,j}} (RTW_{i,j})^{\delta_{4i,j}} \\
& (BRANW_{i,j})^{\delta_{5i,j}} (PULPW_{i,j})^{\delta_{6i,j}} (CAKEW_{i,j})^{\delta_{7i,j}}]^{\xi_{i,j}}
\end{aligned} \tag{3}$$

where $Y_{i,j}$ is the production of sector j in region i . $A_{i,j}$ is the technological parameter of the production of sector j in region i . $KL_{i,j}$, $LB_{i,j}$, $LD1_{i,j}$ and $LD2_{i,j}$ are capital, labour, cropland, and pasture land inputs for production j in region i , respectively. $NFE_{i,j}$, $PFE_{i,j}$, $CER_{i,j}$, $OSD_{i,j}$, $VF_{i,j}$, $RT_{i,j}$, $SGR_{i,j}$, $OTC_{i,j}$, $COF_{i,j}$, $BRAN_{i,j}$, $PULP_{i,j}$, and $CAKE_{i,j}$ are nitrogen fertiliser, phosphorus fertiliser, cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, sugar crops, other non-food crops, compound feed, cereal bran, alcoholic pulp, and oil cake inputs for the production of sector j in region i , respectively. $CERW_{i,j}$, $OSDW_{i,j}$, $VFW_{i,j}$, $RTW_{i,j}$, $BRANW_{i,j}$, $PULPW_{i,j}$, and $CAKEW_{i,j}$ are food waste (i.e., cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, roots & tubers waste, cereal bran waste, alcoholic pup waste, and oil cake waste) recycling service as feed input for the production of sector j in region i , respectively. $\xi_{i,j}$ ($0 < \xi_{i,j} < 1$) is the cost share of food waste for the production of sector j in region i . η_f ($f=1, 2, 3, \dots, 16$) is the cost share of each factor and intermediate input for production, and $\sum_{f=1}^{16} \eta_f = 1$. δ_f ($f=1, 2, 3, \dots, 7$) is the cost share of each food waste input for production, and $\sum_{f=1}^7 \delta_f = 1$.

We also add several additional constraints on the production of crops (i.e., cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, sugar crops, other non-food crops), livestock (i.e., monogastric livestock, ruminant livestock), and food processing by-products (i.e., cereal brans, alcoholic pulps, oil cakes) based on the information from the social accounting matrices (SAM) (see Appendix Tables 2-3) in the base year of 2014 for China and its trading partners.

Crops can't be produced in a "factory-like" setting because the chemical processes within plants require specific nutrients that can't be substituted for one another. Different combinations of nutrients, such as nitrogen (N) and phosphorus (P_2O_5), lead to varying crop yields. Thus, we kept the total output of crop as a fixed ratio of nitrogen and phosphorus fertiliser inputs. In other words, the ratio of nitrogen and phosphorus fertiliser inputs for per unit of crop output remained constant across all scenarios. Since livestock productivity is directly tied to the protein and energy levels of feed, the total output of livestock is a fixed ratio of feed inputs. When substituting primary feed (i.e., human-edible feed crops and compound feed) with food waste and food processing by-products, the protein and energy feed supplies per unit of animal output were kept constant in all scenarios. Since food processing by-products are calculated based on the consumption of food products and specific technical conversion factors, we maintained a constant ratio of by-product output to the consumption of corresponding food products across all scenarios.

When emissions are outputs of the production process, the emissions intensities of greenhouse gases (GHGs) ($\varepsilon_{gg,i,j}$, kg CO₂ equivalent USD⁻¹), acidification pollutants ($\varepsilon_{ga,i,j}$, kg NH₃ equivalent USD⁻¹), and eutrophication pollutants (EP, $\varepsilon_{ge,i,j}$, kg N equivalent USD⁻¹) from producer j in region i are calculated as:

$$\varepsilon_{gg,i,j} = \frac{EM_{gg,i,j}^{+0}}{Y_{i,j}^0} \quad (4)$$

$$\varepsilon_{ga,i,j} = \frac{EM_{ga,i,j}^{+0}}{Y_{i,j}^0} \quad (5)$$

$$\varepsilon_{ge,i,j} = \frac{EM_{ge,i,j}^{+0}}{Y_{i,j}^0} \quad (6)$$

where $EM_{gg,i,j}^{+0}$ is the emissions of GHGs gg ($gg=CO_2$, CH_4 , and N_2O emissions) from producer j in region i in the base run. $EM_{ga,i,j}^{+0}$ is the emissions of acidification pollutants ga ($ga=NH_3$, NO_x , and SO_2 emissions) from producer j in region i in the base run. $EM_{ge,i,j}^{+0}$ is the emissions of eutrophication pollutants ge ($ge= N$ and P losses) from producer j in region i in the base run. $Y_{i,j}^0$ is the production of producer j in region i in the base run.

Next, the emissions in different scenarios are calculated by multiplying the current production level by corresponding emission intensities. The total emissions of GHGs, acidification and eutrophication pollutants from all producers in region i are calculated as follows:

$$EMG_{i,j}^+ = \sum_{gg} \varepsilon_{gg,i,j} * Y_{i,j} * Eqv_{gg}$$

for emissions of GHGs $gg = CO_2$, CH_4 , and N_2O emissions

(7)

$$EMA_{i,j}^+ = \sum_{ga} \varepsilon_{ga,i,j} * Y_{i,j} * Eqv_{ga}$$

for emissions of acidification pollutants $ga = NH_3$, NO_x , and SO_2 emissions

(8)

$$EME_{i,j}^+ = \sum_{ge} \varepsilon_{ge,i,j} * Y_{i,j} * Eqv_{ge}$$

for emissions of eutrophication pollutants $ge = N$ and P losses

(9)

where $EMG_{i,j}^+$, $EMA_{i,j}^+$, and $EME_{i,j}^+$ are the total emissions of GHGs, acidification and eutrophication pollutants from producer j in region i , respectively. Eqv_{gg} , Eqv_{ga} , and Eqv_{ge} are the GWP, AP, and EP equivalent factors based on Goedkoop, et al. ³.

Balance equations

In our applied model, we consider factor inputs (i.e., capital, labour, and land) to be mobile between different sectors but immobile between China and MTP. Cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, and other non-food crops are used for direct consumption and intermediate use for monogastric livestock, ruminant livestock, compound feed, food processing by-products (i.e., cereal bran, alcoholic pulp, and oil cake), and processed food production. Food processing by-products (i.e., cereal bran, alcoholic pulp, and oil cake) and compound feed are produced for intermediate use for monogastric livestock and ruminant livestock production. Monogastric livestock, ruminant livestock, processed food, and non-food are used for direct consumption. Nitrogen fertiliser and phosphorus fertiliser are used for cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, and other non-food crops production but not for consumption. We note C for consumption, $XNET$ for net export (exports minus imports), and Y for production. Variables with a bar stand for exogenous ones.

International trade is modelled using the assumption of perfect substitutes between domestic and imported goods, adhering to the Heckscher-Ohlin assumption ⁴. With this assumption, production

will take place in countries with comparative advantages, meaning goods will be produced in the countries that can produce them most efficiently. To prevent a strong specialisation effect under free international trade, which could reduce some goods' production to zero in a certain region, we set a lower bound of 10% of the original production for each sector in our model.

The balance equations for cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, and other non-food crops in region i are as follows:

$$C_{i,cer} + CER_{i,oap} + CER_{i,ctl} + CER_{i,cof} + CER_{i,bran} + CER_{i,pulp} + CER_{i,otf} + XNET_{i,cer} \leq Y_{i,cer} (p_{i,cer}) \quad (10)$$

$$C_{i,osd} + OSD_{i,oap} + OSD_{i,ctl} + OSD_{i,cof} + OSD_{i,cake} + OSD_{i,otf} + XNET_{i,osd} \leq Y_{i,osd} (p_{i,osd}) \quad (11)$$

$$C_{i,vf} + VF_{i,oap} + VF_{i,ctl} + VF_{i,cof} + VF_{i,otf} + XNET_{i,vf} \leq Y_{i,vf} (p_{i,vf}) \quad (12)$$

$$C_{i,rt} + RT_{i,oap} + RT_{i,ctl} + RT_{i,cof} + RT_{i,otf} + XNET_{i,rt} \leq Y_{i,rt} (p_{i,rt}) \quad (13)$$

$$C_{i,sgr} + SGR_{i,oap} + SGR_{i,ctl} + SGR_{i,cof} + SGR_{i,otf} + XNET_{i,sgr} \leq Y_{i,sgr} (p_{i,sgr}) \quad (14)$$

$$C_{i,ocr} + OCR_{i,oap} + OCR_{i,ctl} + OCR_{i,cof} + OCR_{i,otf} + XNET_{i,vf} \leq Y_{i,ocr} (p_{i,ocr}) \quad (15)$$

where $CER_{i,oap}$, $CER_{i,ctl}$, $CER_{i,cof}$, $CER_{i,bran}$, $CER_{i,pulp}$, and $CER_{i,otf}$ are cereals used for monogastric livestock, ruminant livestock, compound feed, cereal bran, alcoholic pulp, and processed food production in region i , respectively. $OSD_{i,oap}$, $OSD_{i,ctl}$, $OSD_{i,cof}$, $OSD_{i,bran}$, and $OSD_{i,otf}$ are cereals used for monogastric livestock, ruminant livestock, compound feed, oil cake, and processed food production in region i , respectively. $VF_{i,oap}$, $VF_{i,ctl}$, $VF_{i,cof}$, and $VF_{i,otf}$ are vegetables & fruits used for monogastric livestock, ruminant livestock, compound feed, and processed food production in region i , respectively. $RT_{i,oap}$, $RT_{i,ctl}$, $RT_{i,cof}$, and $RT_{i,otf}$ are roots & tubers used for monogastric livestock, ruminant livestock, compound feed, and processed food production in region i , respectively. $SGR_{i,oap}$, $SGR_{i,ctl}$, $SGR_{i,cof}$, and $SGR_{i,otf}$ are sugar crops used for monogastric livestock, ruminant livestock, compound feed, and processed food production in region i , respectively. $OCR_{i,oap}$, $OCR_{i,ctl}$, $OCR_{i,cof}$, and $OCR_{i,otf}$ are other non-food crops used for monogastric livestock, ruminant livestock, compound feed, and processed food production in region i , respectively. $p_{i,cer}$, $p_{i,osd}$, $p_{i,vf}$, $p_{i,rt}$, $p_{i,sgr}$, and $p_{i,ocr}$ are the shadow prices of cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, and other non-food crops in region i , respectively.

The balance equation for food processing by-products (i.e., cereal bran, alcoholic pulp, and oil cake) in region i is as follows:

$$BRAN_{i,oap} + XNET_{i,bran} \leq Y_{i,bran} (p_{i,bran}) \quad (16)$$

$$PULP_{i,oap} + XNET_{i,pulp} \leq Y_{i,pulp} (p_{i,pulp}) \quad (17)$$

$$CAKE_{i,oap} + XNET_{i,cake} \leq Y_{i,cake} (p_{i,cake}) \quad (18)$$

where $BRAN_{i,oap}$, $PULP_{i,oap}$, and $CAKE_{i,oap}$ are cereal bran, alcoholic pulp, and oil cake used for monogastric livestock production in region i , respectively. $p_{i,bran}$, $p_{i,pulp}$, and $p_{i,cake}$ are the shadow prices of cereal bran, alcoholic pulp, and oil cake in region i .

The balance equation for compound feed in region i is as follows:

$$COF_{i,oap} + COF_{i,ctl} + XNET_{i,cof} \leq Y_{i,cof} \quad (p_{i,cof}) \quad (19)$$

where $COF_{i,oap}$ and $COF_{i,ctl}$ are compound feed used in monogastric livestock and ruminant livestock production in region i , respectively. $p_{i,cof}$ is the shadow price of compound feed in region i .

The balance equation for monogastric livestock, ruminant livestock, processed food, and non-food in region i is as follows:

$$C_{i,j} + XNET_{i,j} \leq Y_{i,j} \quad (p_{i,j}) \quad (20)$$

where $p_{i,j}$ is the shadow price of good j in region i .

The balance equation for nitrogen and phosphorus fertiliser in region i is as follows:

$$NFE_{i,cer} + NFE_{i,osd} + NFE_{i,vf} + NFE_{i,rt} + NFE_{i,sg} + NFE_{i,ocr} + XNET_{i,nfe} \leq Y_{i,nfe} \quad (p_{i,nfe}) \quad (21)$$

$$PFE_{i,cer} + PFE_{i,osd} + PFE_{i,vf} + PFE_{i,rt} + PFE_{i,sg} + PFE_{i,ocr} + XNET_{i,pfe} \leq Y_{i,pfe} \quad (p_{i,pfe}) \quad (22)$$

where $NFE_{i,cer}$, $NFE_{i,osd}$, $NFE_{i,vf}$, $NFE_{i,rt}$, $NFE_{i,sg}$ and $NFE_{i,ocr}$ are the nitrogen fertiliser used for cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, and other non-food crops production in region i , respectively. $PFE_{i,cer}$, $PFE_{i,osd}$, $PFE_{i,vf}$, $PFE_{i,rt}$, $PFE_{i,sg}$ and $PFE_{i,ocr}$ are the phosphorus fertiliser used for cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, and other non-food crops production in region i , respectively. $p_{i,nfe}$ and $p_{i,pfe}$ are the shadow prices of nitrogen fertiliser and phosphorus fertiliser in region i , respectively.

For trade balance of all goods:

$$\sum_i XNET_{i,j} = 0 \quad (p_j) \quad (23)$$

In the applied model, we assume that factor endowments (i.e., capital, labour, cropland, and pasture land) are mobile between different sectors but immobile among the two regions. For the balance equations of production factor inputs:

$$\sum_j KL_{i,j} \leq \overline{KL}_i \quad (r_i) \quad (24)$$

$$\sum_j LB_{i,j} \leq \overline{LB}_i \quad (w_i) \quad (25)$$

$$\sum_j LD1_{i,j} \leq \overline{LD1}_i \quad (k1_i)$$

for sector j = cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, and other non-food crops

$$(26)$$

$$\sum_j LD2_{i,j} \leq \overline{LD2}_i \quad (k2_i)$$

for sector j = ruminant livestock

$$(27)$$

where \overline{KL}_i , \overline{LB}_i , $\overline{LD1}_i$ and $\overline{LD2}_i$ are the factor endowments (i.e., capital, labour, cropland, pasture land) supply in region i , respectively. r_i , w_i , $k1_i$, and $k2_i$ are the shadow prices of capital, labour, cropland, and pasture land in region i , respectively.

If an emission permit system is implemented to control the total emissions of GHGs, acidification and eutrophication pollutants from all producers, then the following relationship holds:

$$\sum_j EMG_{i,j}^+ \leq \overline{TMG}_i^+ \quad (p_{eg,i}) \quad (28)$$

$$\sum_j EMA_{i,j}^+ \leq \overline{TMA}_i^+ \quad (p_{ea,i}) \quad (29)$$

$$\sum_j EME_{i,j}^+ \leq \overline{TME}_i^+ \quad (p_{ee,i}) \quad (30)$$

where TMG_i^+ , TMA_i^+ , and TME_i^+ are the total emissions of GHGs, acidification and eutrophication pollutants from all producers in region i , respectively. \overline{TMG}_i^+ , \overline{TMA}_i^+ , and \overline{TME}_i^+ are the permitted level of the total emissions of GHGs, acidification and eutrophication pollutants in region i , respectively. Emissions should not be above a certain level for the regeneration of the environment. For benchmarking, the permitted emission level is the total emission level in the base year. For an environmental policy study (scenarios S3-4), the permitted emission level can be an exogenous emission permit determined by the ecological limit. $p_{eg,i}$, $p_{ea,i}$, and $p_{ee,i}$ are the shadow prices of the emissions of GHGs, acidification and eutrophication pollutants in region i , respectively.

Monogastric livestock's total demand for food waste recycling service must be equal to or less than the total supply of food waste recycling service, then the following relationship holds:

$$CERW_{i,oap} \leq \overline{CERW}_{i,oap} \quad (p_{i,cerw1}) \quad (31)$$

$$OSDW_{i,oap} \leq \overline{OSDW}_{i,oap} \quad (p_{i,osdw1}) \quad (32)$$

$$VFW_{i,oap} \leq \overline{VFW}_{i,oap} \quad (p_{i,vfw1}) \quad (33)$$

$$RTW_{i,oap} \leq \overline{RTW}_{i,oap} \quad (p_{i,rtw1}) \quad (34)$$

$$BRANW_{i,oap} \leq \overline{BRANW}_{i,oap} \quad (p_{i,branw1}) \quad (35)$$

$$PULPW_{i,oap} \leq \overline{PULPW}_{i,oap} \quad (p_{i,pulpw1}) \quad (36)$$

$$CAKEW_{i,oap} \leq \overline{CAKEW}_{i,oap} \quad (p_{i,cakew1}) \quad (37)$$

where $\overline{CERW}_{i,oap}$, $\overline{OSDW}_{i,oap}$, $\overline{VFW}_{i,oap}$, $\overline{RTW}_{i,oap}$, $\overline{BRANW}_{i,oap}$, $\overline{PULPW}_{i,oap}$, and $\overline{CAKEW}_{i,oap}$ are the total supply of food waste (i.e., cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, roots & tubers waste, cereal bran waste, alcoholic pup waste, and oil cake waste) recycling service. $p_{i,cerw1}$, $p_{i,osdw1}$, $p_{i,vfw1}$, $p_{i,rtw1}$, $p_{i,branw1}$, $p_{i,pulpw1}$, and $p_{i,cakew1}$ are the shadow prices of food waste (i.e., cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, roots & tubers waste, cereal bran waste, alcoholic pup waste, and oil cake waste) recycling service.

Consumer's total demand for food waste collection service must be equal to or less than the total supply of food waste collection service, then the following relationship holds:

$$C_{i,cerw} \leq \overline{C}_{i,cerw} \quad (p_{i,cerw2}) \quad (38)$$

$$C_{i,osdw} \leq \overline{C_{i,osdw}} \quad (p_{i,osdw2}) \quad (39)$$

$$C_{i,vfw} \leq \overline{C_{i,vfw}} \quad (p_{i,vfw2}) \quad (40)$$

$$C_{i,rtw} \leq \overline{C_{i,rtw}} \quad (p_{i,rtw2}) \quad (41)$$

$$C_{i,branw} \leq \overline{C_{i,branw}} \quad (p_{i,branw2}) \quad (42)$$

$$C_{i,pulpw} \leq \overline{C_{i,pulpw}} \quad (p_{i,pulpw2}) \quad (43)$$

$$C_{i,cakew} \leq \overline{C_{i,cakew}} \quad (p_{i,cakew2}) \quad (44)$$

where $C_{i,cerw}$, $C_{i,osdw}$, $C_{i,vfw}$, $C_{i,rtw}$, $C_{i,branw}$, $C_{i,pulpw}$, and $C_{i,cakew}$ are the total supply of food waste (i.e., cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, roots & tubers waste, cereal bran waste, alcoholic pup waste, and oil cake waste) collection service. $p_{i,cerw2}$, $p_{i,osdw2}$, $p_{i,vfw2}$, $p_{i,rtw2}$, $p_{i,branw2}$, $p_{i,pulpw2}$, and $p_{i,cakew2}$ are the shadow prices of food waste (i.e., cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, roots & tubers waste, cereal bran waste, alcoholic pup waste, and oil cake waste) collection service.

Budget constraint

The budget constraint for a consumer i holds such that the expenditure must be equal to the income:

$$\sum_s (p_{i,s} C_{i,s}) + p_{i,cerw2} C_{i,cerw} + p_{i,osdw2} C_{i,osdw} + p_{i,vfw2} C_{i,vfw} + p_{i,rtw2} C_{i,rtw} + p_{i,branw2} C_{i,branw} + p_{i,pulpw2} C_{i,pulpw} + p_{i,cakew2} C_{i,cakew} = h_i \quad (45)$$

where consumption goods s refers to cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, sugar crops, other non-food crops, monogastric livestock, ruminant livestock, processed food, and non-food. $\sum_s (p_{i,s} C_{i,s})$ is the total expenditure on the consumption goods in region i . $p_{i,cerw2} C_{i,cerw}$, $p_{i,osdw2} C_{i,osdw}$, $p_{i,vfw2} C_{i,vfw}$, $p_{i,rtw2} C_{i,rtw}$, $p_{i,branw2} C_{i,branw}$, $p_{i,pulpw2} C_{i,pulpw}$, and $p_{i,cakew2} C_{i,cakew}$ are the payments to the food waste (i.e., cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, roots & tubers waste, cereal bran waste, alcoholic pup waste, and oil cake waste) collection service in region i . The Negishi weight (α_i) in the welfare function (equation 1) will be chosen such that the budget constraints hold for each representative consumer in region i .

Consumer's income is the sum of the remuneration of initial endowments employed in production and payments to the environmental sector. Given that food waste is either consumed by livestock as feed or consumed by consumers as a cost of collecting food waste from the municipality, we should also include income from food waste treatment. Since goods are tradable, the consumer's income should exclude the export part. Thus, the consumer's income is:

$$\begin{aligned} h_i = & r_i \overline{KL}_i + w_i \overline{LB}_i + k_{1i} \overline{LD1}_i + k_{2i} \overline{LD2}_i - \sum_j (p_j XNET_{i,j}) + p_{i,cerw1} CERW_{i,oap} + \\ & p_{i,osdw1} OSDW_{i,oap} + p_{i,vfw1} VFW_{i,oap} + p_{i,rtw1} RTW_{i,oap} + p_{i,branw1} BRANW_{i,oap} + \\ & p_{i,pulpw1} PULPW_{i,oap} + p_{i,cakew1} CAKEW_{i,oap} + p_{i,cerw2} C_{i,cerw} + p_{i,osdw2} C_{i,osdw} + \\ & p_{i,vfw2} C_{i,vfw} + p_{i,rtw2} C_{i,rtw} + p_{i,branw2} C_{i,branw} + p_{i,pulpw2} C_{i,pulpw} + p_{i,cakew2} C_{i,cakew} + \\ & p_{eg,i} \overline{TMG}_i^+ + p_{ea,i} \overline{TMA}_i^+ + p_{ee,i} \overline{TME}_i^+ \end{aligned} \quad (46)$$

where $\sum_j (p_j XNET_{i,j})$ is the income from exports. $p_{i,cerw1} CERW_{i,oap}$, $p_{i,osdw1} OSDW_{i,oap}$, $p_{i,vfw1} VFW_{i,oap}$, $p_{i,rtw1} RTW_{i,oap}$, $p_{i,branw1} BRANW_{i,oap}$, $p_{i,pulpw1} PULPW_{i,oap}$, and $p_{i,cakew1} CAKEW_{i,oap}$ are the income from food waste recycling service in region i . $p_{i,cerw2} C_{i,cerw}$, $p_{i,osdw2} C_{i,osdw}$, $p_{i,vfw2} C_{i,vfw}$, $p_{i,rtw2} C_{i,rtw}$, $p_{i,branw2} C_{i,branw}$, $p_{i,pulpw2} C_{i,pulpw}$, and $p_{i,cakew2} C_{i,cakew}$ are the income from food waste collection service in

region i . $p_{eg,i}\overline{TMG}_i^+$, $p_{ea,i}\overline{TMA}_i^+$, and $p_{ee,i}\overline{TME}_i^+$ are the income from selling emission permits of GHGs, acidification and eutrophication pollutants.

The producers' profits are specified as follows:

$$\begin{aligned} PROF_{i,j} = & p_j Y_{i,j} - r_i KL_{i,j} - w_i LB_{i,j} - k1_i LD1_{i,j} - k2_i LD2_{i,j} - p_{cer} CER_{i,j} - p_{osd} OSD_{i,j} - \\ & p_{vf} VF_{i,j} - p_{rt} RT_{i,j} - p_{sgr} SGR_{i,j} - p_{ocr} OCR_{i,j} - p_{cof} COF_{i,j} - p_{bran} BRAN_{i,j} - p_{pulp} PULP_{i,j} - \\ & p_{cake} CAKE_{i,j} - p_{nfe} NFE_{i,j} - p_{pfe} PFE_{i,j} - p_{i,cerw1} CERW_{i,oap} - p_{i,osdw1} OSDW_{i,oap} - \\ & p_{i,vfw1} VFW_{i,oap} - p_{i,rtw1} RTW_{i,oap} - p_{i,branw1} BRANW_{i,oap} - p_{i,pulpw1} PULPW_{i,oap} - \\ & p_{i,cakew1} CAKEW_{i,oap} - p_{eg,i} EMG_{i,j}^+ - p_{ea,i} EMA_{i,j}^+ - p_{ee,i} EME_{i,j}^+ \end{aligned} \quad (47)$$

Model calibration

As in the literature on AGE models, we followed the Harberger convention ⁵ to calibrate the model using the base year SAMs. It means that the prices of all goods and factors are set to one, and the quantities of consumption and production goods equal the monetary value of the base year SAMs ⁶. We calibrate the parameters in production and utility functions based on the cost shares of inputs in total production output and expenditure shares of consumption goods in total expenditure. In order to calibrate food waste-related parameters and add food waste (i.e., cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, roots & tubers waste, cereal bran waste, alcoholic pup waste, and oil cake waste) into the SAMs (see Appendix Tables 2-3), our model treats food waste recycling service as feed input for monogastric livestock production (see equation 3), and assumes that consumer buys food waste collection service for consumption (see equation 45).

Definition of scenarios

S0 - Baseline

The baseline (S0) represents the economies of China and MTP in 2014. The total amounts of food waste and food processing by-products and their current use as animal feed and discarded biomass (i.e., landfill and incineration) for China in S0 are presented in Supplementary Tables 4. When substituting primary feed (i.e., feed crops and compound feed) in animal diets with food waste and food processing by-products, the total protein and total energy supplies per unit of animal output were kept constant in all scenarios. The cost of increasing the supply of food waste recycling service was modelled as a rising percentage of the initial cost of recycling food waste and food processing by-products as feed (54 dollar ton⁻¹), while the cost of decreasing the supply of food waste collection service was modelled as a declining percentage of the initial cost of collecting food waste and food processing by-products for landfill and incineration (82 dollar ton⁻¹). Physical quantities and prices of food waste recycling service and food waste collection service in China were presented in Supplementary Tables 4-5.

S1 - Partial use of food waste and food processing by-products as feed

Scenario S1 investigated the impacts of upcycling partial food waste and food processing by-products as feed (54% of food waste and 100% of food processing by-products allowed to be used as feed for monogastric livestock). In S1, cross-provincial transportation of food waste was not

allowed, which limits the maximum utilisation rate of food waste with high moisture content to 54% in China, according to Fang, et al. ⁷.

S2 - Full use of food waste and food processing by-products as feed

Scenario S2 analysed the impacts of upcycling full food waste and food processing by-products as feed (100% of food waste and 100% of food processing by-products allowed to be used as feed for monogastric livestock), taking into account economies of scale. In S2, cross-provincial transportation of food waste was allowed in S2. Economies of scale in food waste recycling were considered in S2, where a 1% increase in recycled waste resulted in only a 0.078% rise in recycling costs, indicating that increasing the amount of recycled waste might not necessarily incur additional costs, as reported by Cialani and Mortazavi ⁸. This is because, initially, recycling entails high fixed costs, yet as production scales up, marginal costs decrease and then stabilise.

S3 - S1 + A modest emission mitigation target

In S3, the equations below showed that the total emissions of GHGs, acidification and eutrophication pollutants from all sectors j in both China and MTP were no more than their baseline (S0) emission levels.

$$\sum_j EMG_{i,j}^+ \leq \overline{TMG_i^+} \quad (p_{eg,i}) \quad (48)$$

$$\sum_j EMA_{i,j}^+ \leq \overline{TMA_i^+} \quad (p_{ea,i}) \quad (49)$$

$$\sum_j EME_{i,j}^+ \leq \overline{TME_i^+} \quad (p_{ee,i}) \quad (50)$$

S4 - S1 + An ambitious emission mitigation target

In S4, the equations below showed that the total emissions of GHGs, acidification and eutrophication pollutants from all sectors j in both China and MTP were no more than the emission thresholds set by China's and MTP's annual GHG mitigation targets under the Intended Nationally Determined Contributions (INDC) of the Paris Agreement ^{9,10}, as well as China's emission reduction goals for acidification and eutrophication pollutants in line with the "14th Five-Year Plan" ¹¹.

$$\sum_j EMG_{CN,j}^+ \leq 0.974 * \overline{TMG_i^+} \quad (p_{eg,i}) \quad (51)$$

$$\sum_j EMG_{MTP,j}^+ \leq 0.98 * \overline{TMG_i^+} \quad (p_{eg,i}) \quad (52)$$

$$\sum_j EMA_{CN,j}^+ \leq 0.975 * \overline{TMA_i^+} \quad (p_{ea,i}) \quad (53)$$

$$\sum_j EMA_{MTP,j}^+ \leq \overline{TMA_i^+} \quad (p_{ea,i}) \quad (54)$$

$$\sum_j EME_{CN,j}^+ \leq 0.98 * \overline{TME_i^+} \quad (p_{ee,i}) \quad (55)$$

$$\sum_j EME_{MTP,j}^+ \leq \overline{TME_i^+} \quad (p_{ee,i}) \quad (56)$$

Supplementary Results

Results related to crop production

The expansion of monogastric livestock production, a relatively labour-intensive sector, increased labour demand, leading to a 0.13-0.22% rise in average wages across the Chinese economy (Supplementary Fig. 5a). Consequently, labour became comparatively more expensive than other inputs (i.e., capital, cropland, and fertilisers). As cropland and fertilisers became relatively cheaper, crop producers were incentivised to engage in crop extensification and use more cropland and fertilisers to substitute labour. This led to a 0.8-2.3% increase in total N fertiliser use, a 0.8-2.8% increase in total P fertiliser use (Supplementary Fig. 4a,b). Crop producers will prioritise reducing the production of relatively labour-intensive crops; for example, roots & tubers and sugar crops decreased by 6-90% and by 15-32% (Supplementary Fig. 6). The saved cropland would then be reallocated to increase the production of cereal grains by 0.8-1.5%, vegetables and fruits by 1.7-2.7%, and other non-food crops by 8-18% (Supplementary Fig. 6). Notably, the production of oilseeds & pulses decreased by 1.6% with partial upcycling but increased by 95% with full upcycling. This variation occurs because oilseeds & pulses are both relatively labour-intensive and cropland-intensive compared to other crops, making their production dependent on the interplay between labour and cropland costs at different levels of upcycling.

Supplementary Discussion

Limitations and future outlook

First, our study assumes free international trade, full mobility of factor endowments (capital, labour, and land) across sectors, and constant income elasticities for all consumption goods. Neglecting trade barriers in our analysis may overestimate the extent of international trade of feed and food. Barriers to the movement of factor endowments across sectors could be included, for example, by introducing separate labour and capital markets for agricultural and non-agricultural sectors or allowing for land shifts within agroecological zones with similar soil, landform, and climatic features, as included in the MAGNET ¹² and GTAP-AEZ ¹³ models. Second, extending our modelling framework to include additional feed types like maize silage, alfalfa hay, and roughage-like by-products would improve the assessment of nutritional balances, particularly in the context of ruminant livestock production. Since these feeds are primarily used for ruminant livestock, which is not our main focus, this falls outside the scope of our study. Third, our analysis concentrates on scenarios outlining technically and physically possible options and does not endeavour to depict policy instruments for achieving the goal of increased utilisation of food waste and food processing by-products as feed, aligning with previous literature on feeding animals with food waste and food processing by-products ^{7,14-16}. How to design and implement policies that can achieve the goal of increased utilisation of food waste and food processing by-products as feed and implementation of emission taxes should be a pivotal direction for future research. Fourth, in line with SDG 12.3 ("halving food waste") ¹⁷, high priority should be placed on reducing food waste. With less food waste available for animal feed, the impacts of upcycling food waste as feed may diminish. However, we consider our estimates of the impacts of upcycling food waste as feed as conservative, as we did not factor in cross-provincial transportation of food waste with high moisture content (except in

scenario S2). Last but not least, health impacts resulting from changes in food consumption, such as diet- and weight-related risks ¹⁸, could also be considered.

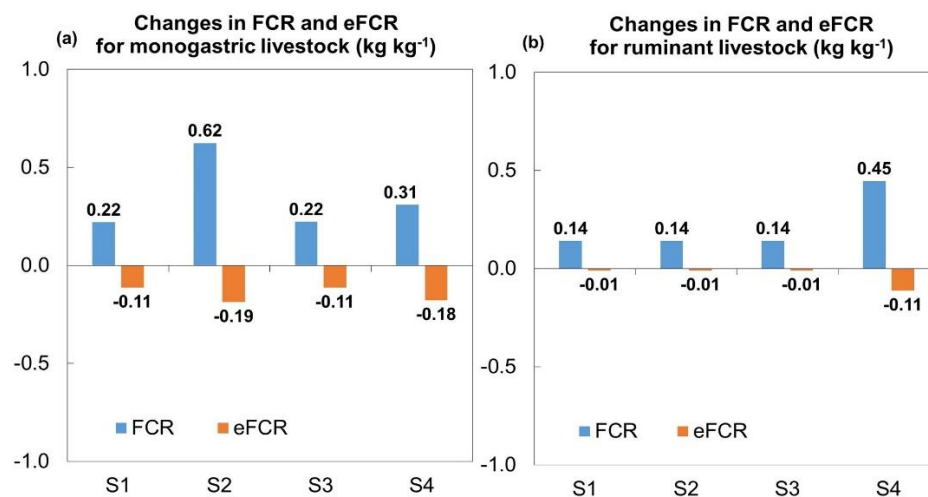

Supplementary Figures

Supplementary Fig. 1 | Total (a) crop, (b) livestock, and (c) fertiliser consumption (Tg) in scenarios. Total crop consumption exclude food waste and food processing by-products used by “food waste recycling service” and “food waste collection service” sectors (see Supplementary Table 4 for detailed data). Total crop consumption includes crop used for intermediate use (i.e, feed crops, compound feed, food processing by-products, processed food) and direct consumption (i.e., primary fresh food).

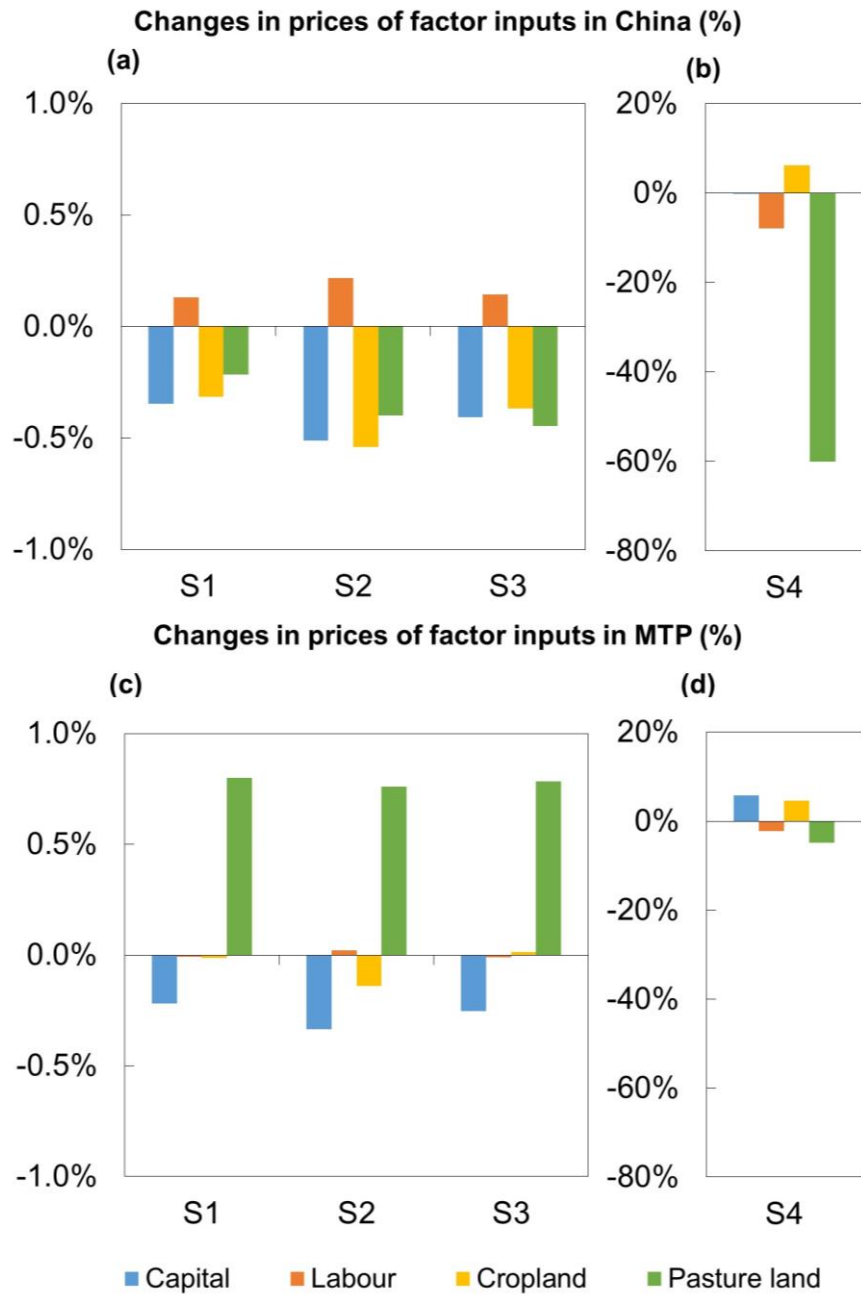

Supplementary Fig. 2 | Shares (%) of each type of feed within the total feed use for monogastric livestock production, categorized by (a) fresh matter, (b) dry matter, (c) protein, and (d) energy in China in scenarios.

Supplementary Fig. 3 | Changes in FCR (kg kg⁻¹) and eFCR (kg kg⁻¹) for (a) monogastric livestock and (b) ruminant livestock production in China in scenarios with respect to the baseline (S0).

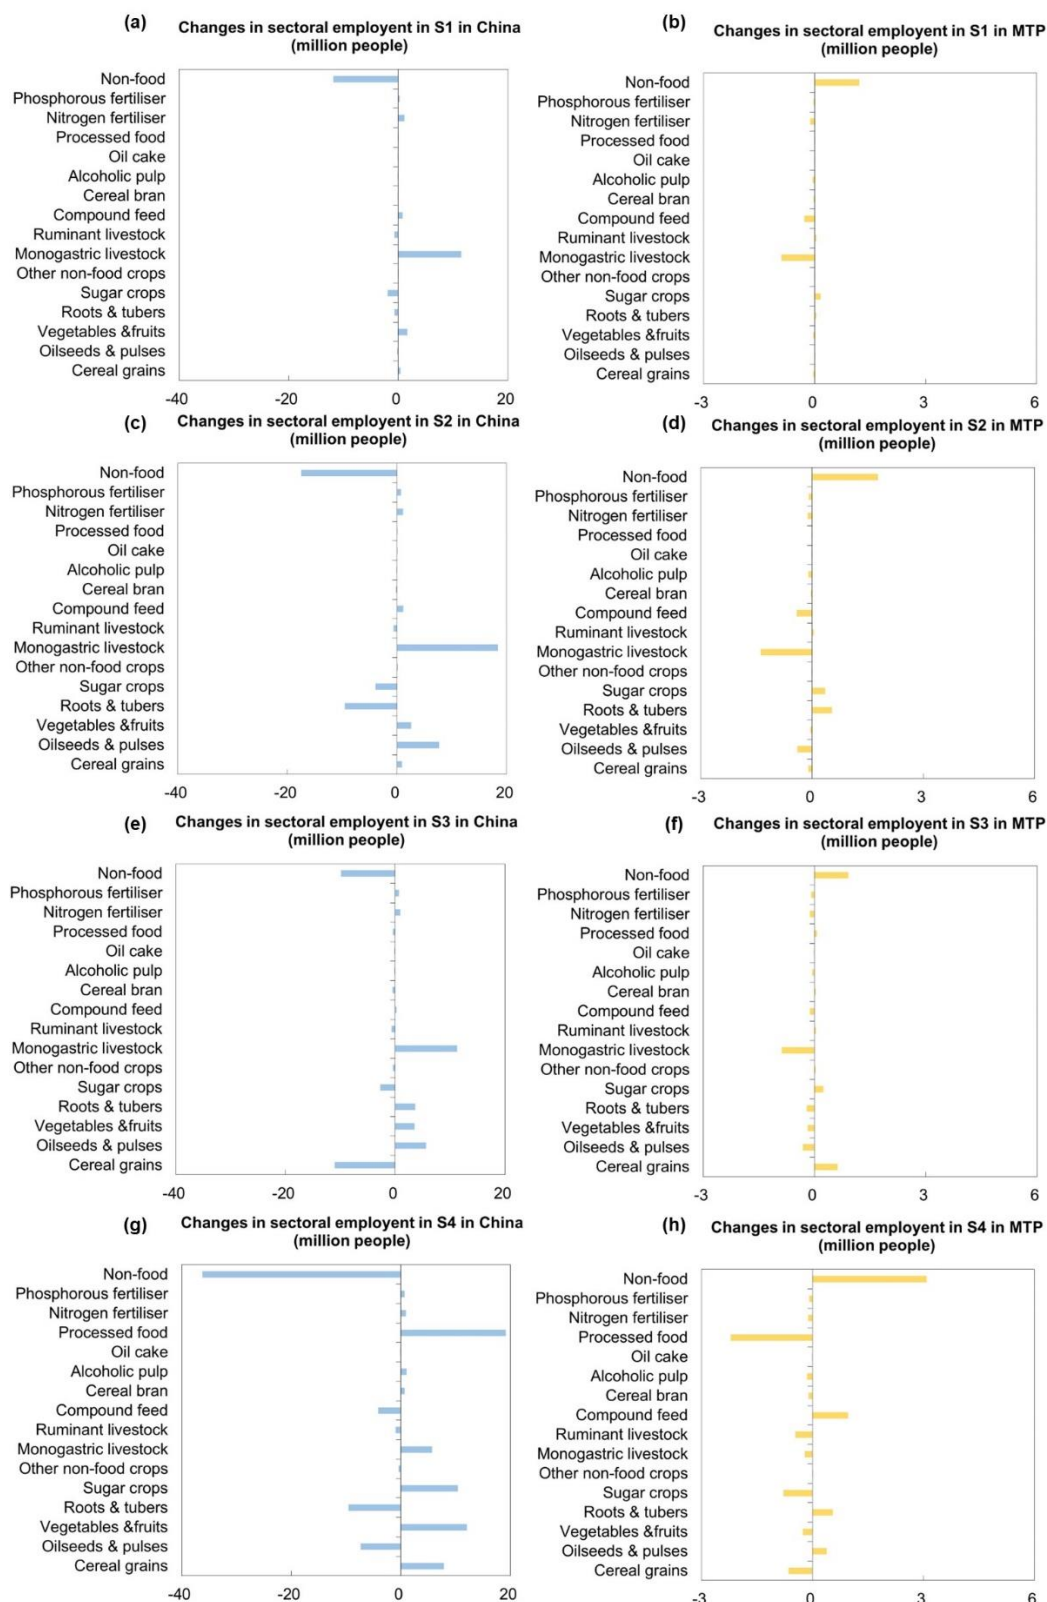

Supplementary Fig. 4 | (a) Total nitrogen fertiliser use (Tg), (b) phosphorous fertiliser use (Tg), (c) crop consumption (Tg), and (d) feed demand by ruminant livestock (Tg) in scenarios..

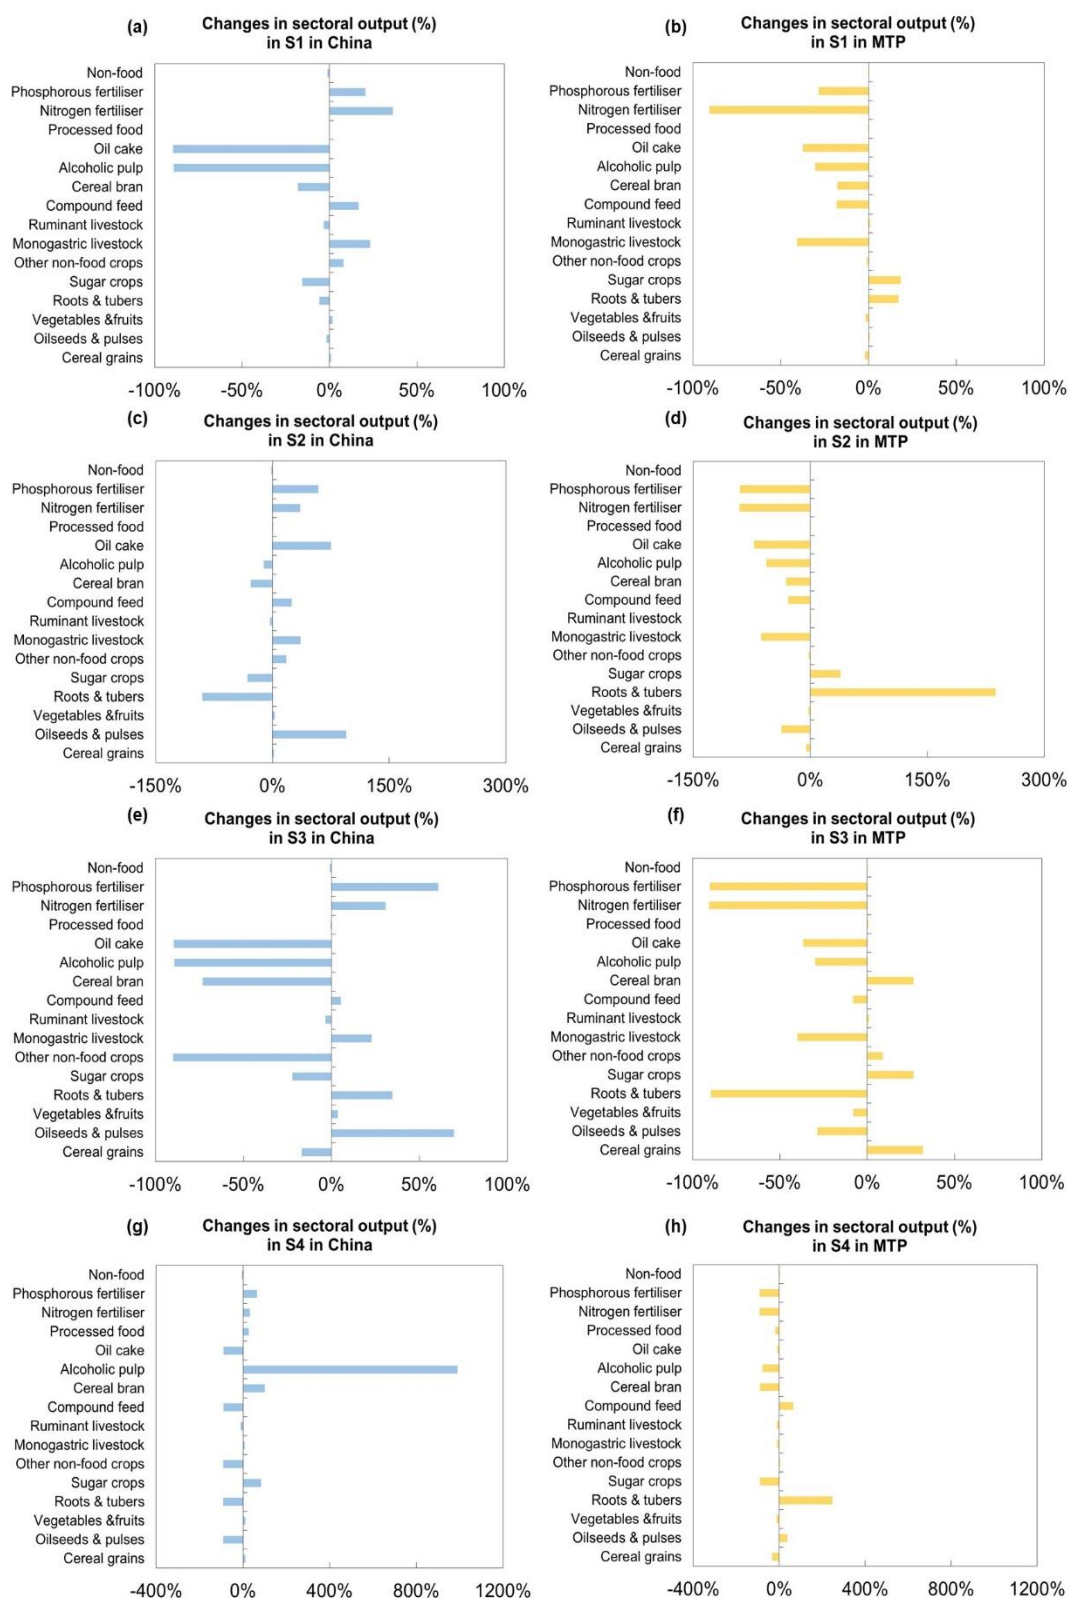

Supplementary Fig. 5 | Changes (%) in prices of factor inputs in China in scenarios (a) S1-3 and (b) S4 with respect to the baseline (S0). Changes (%) in prices of factor inputs in MTP in scenarios (c) S1-3 and (d) S4 with respect to the baseline (S0).

Supplementary Fig. 6 | (a) Shares (%) of each type of crop within the total cropland use in China in scenarios. (b) Changes (Tg) in crop production in China in scenarios with respect to the baseline (S0).

Supplementary Fig. 7 | Changes (million people) in sectoral employment in China in scenarios (a) S1, (c) S2, (e) S3, and (g) S4 with respect to the baseline (S0). Changes (million people) in sectoral employment in MTP in scenarios (b) S1, (d) S2, (f) S3, and (h) S4 with respect to the baseline (S0).

Supplementary Fig. 8 | Changes (%) in sectoral output (i.e., the value of production) in China in scenarios (a) S1, (c) S2, (e) S3, and (g) S4 with respect to the baseline (S0). Changes (%) in sectoral output (i.e., the value of production) in MTP in scenarios (b) S1, (d) S2, (f) S3, and (h) S4 with respect to the baseline (S0).

Supplementary Fig. 9 | Changes (billion USD) in sectoral value-added (a) in China and (b) MTP in scenarios with respect to the baseline (S0).

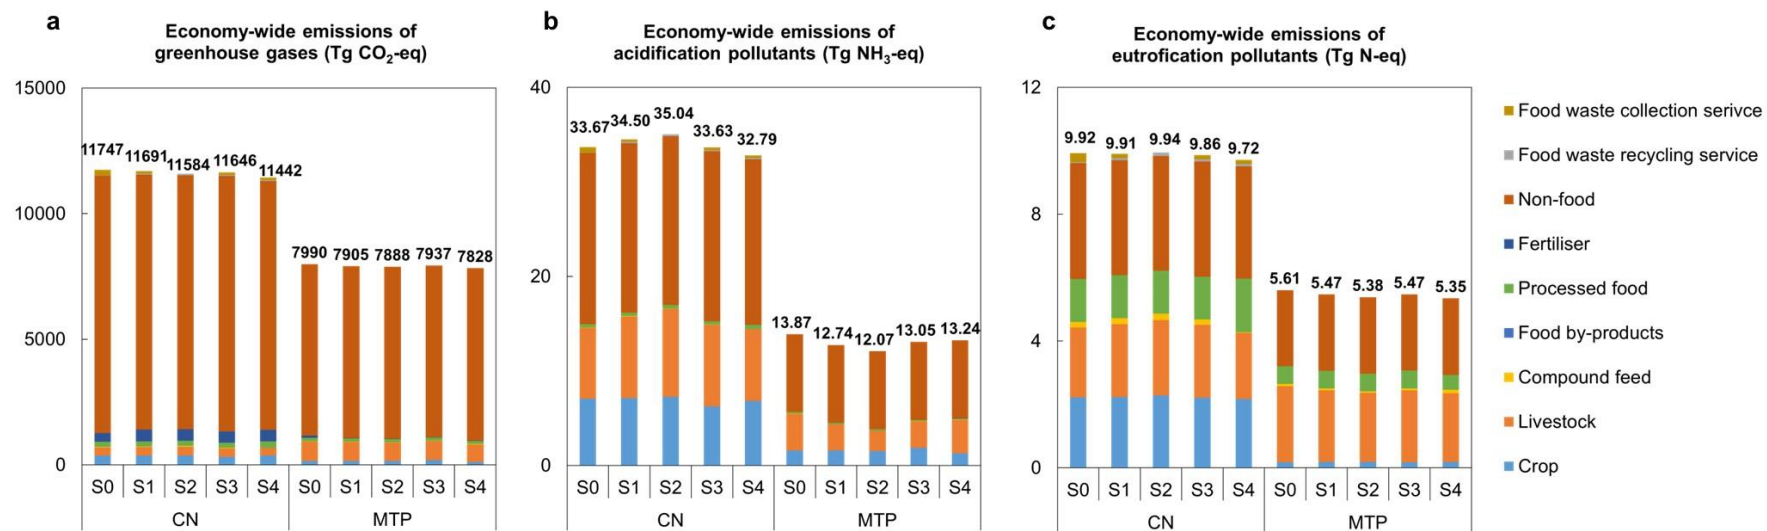

Supplementary Fig. 10 | Shares (%) of sectoral value-added in (a) China and (b) MTP in scenarios.

Supplementary Fig. 11 | (a) Absolute changes (billion USD) and (b) relative changes (%) in gross domestic product (GDP) in China in scenarios with respect to the baseline (S0). (c) Absolute changes (billion USD) and (d) relative changes (%) in gross domestic product (GDP) in MTP in scenarios with respect to the baseline (S0).

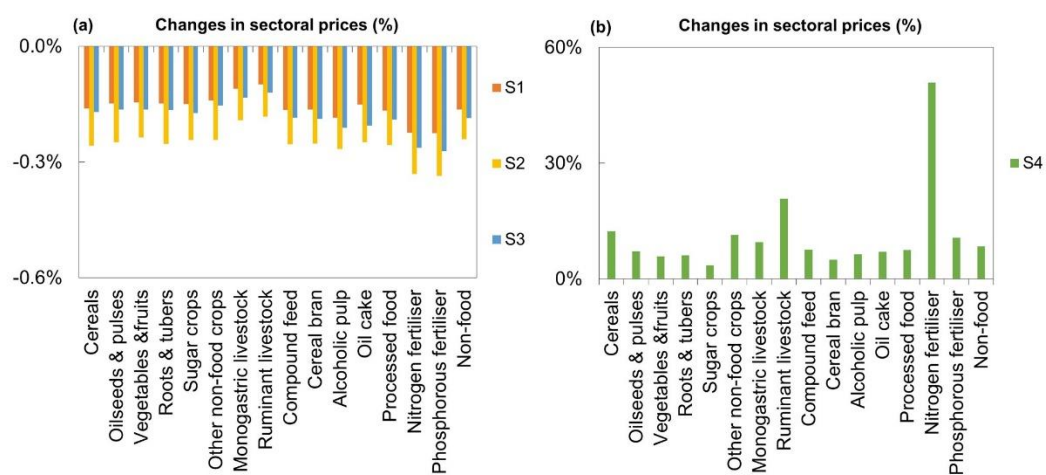

Supplementary Fig. 12 | Changes (%) in (a) household welfare and (b) household expenditure in China in scenarios with respect to the baseline (S0). Changes (%) in (c) household welfare and (d) household expenditure in MTP in scenarios with respect to the baseline (S0).

Supplementary Fig. 13 | (a) Economy-wide emissions of greenhouse gases (Tg CO₂-eq), (b) acidification pollutants (Tg NH₃-eq), and (c) eutrophication pollutants (Tg N-eq) in China and MTP in scenarios.

Supplementary Fig. 14 | Changes in crop emissions of (a) greenhouse gases (Tg CO₂-eq), (b) acidification pollutants (Tg NH₃-eq), and (c) eutrophication pollutants (Tg N-eq) in China and MTP in scenarios with respect to the baseline (S0). Changes in livestock emissions of (d) greenhouse gases (Tg CO₂-eq), (e) acidification pollutants (Tg NH₃-eq), and (f) eutrophication pollutants (Tg N-eq) in China and MTP in scenarios with respect to the baseline (S0). Changes in non-agriculture emissions of (g) greenhouse gases (Tg CO₂-eq), (h) acidification pollutants (Tg NH₃-eq), and (i) eutrophication pollutants (Tg N-eq) in China and MTP in scenarios with respect to the baseline (S0).

Supplementary Fig. 16 | Composition of food availability (%; kcal capita⁻¹ day⁻¹) in (a) China and (b) MTP in the baseline (S0). Changes in food availability (kcal capita⁻¹ day⁻¹) in (c) China and (d) MTP in scenarios with respect to the baseline (S0).

Supplementary Tables

Supplementary Table 1 | Summary of key assumptions used in scenario narratives and compensatory measures in China.

Scenarios ^a	Food waste used as animal feed in its total supply ^b	Emission mitigation target
S0: Baseline	Food waste: 39% By-products: 51%	No
S1: Partial use of food waste and food processing by-products as feed ^c	Food waste: 54% By-products: 100%	No
S2: Full use of food waste and food processing by-products as feed ^c	Food waste: 100% By-products: 100%	No
S3: S1 + A modest emission mitigation target ^d	Food waste: 54% By-products: 100%	Implementing economy-wide emission taxes to control emissions of greenhouse gases, acidification pollutants, and eutrophication pollutants in both China and its main food and feed trading partners (MTP, including Brazil, the United States, and Canada) no more than their baseline (S0) levels.
S4: S1 + An ambitious emission mitigation target ^d	Food waste: 54% By-products: 100%	Implementing economy-wide emission taxes to reduce emissions of greenhouse gases by 2.6% in China and 2.0% in MTP in line with their annual mitigation target of Intended Nationally Determined Contributions (INDC) under the Paris Agreement ^{9,10} . Implementing economy-wide emission taxes to reduce emissions of acidification and eutrophication pollutants in China by 2.5% and 2.0%, respectively, according to the annual mitigation target set by China's "14 th Five-Year Plan" ¹¹ . Implementing economy-wide emission taxes to control emissions of acidification and eutrophication pollutants in MTP no more than the baseline (S0) level.

^a When substituting primary feed (i.e., feed crops and compound feed) in animal diets with food waste and food processing by-products, the total protein and total energy supplies per unit of animal output were kept constant in all scenarios.

^b In S1, cross-provincial transportation of food waste with high moisture content was not allowed, which limits the maximum utilisation rate of food waste to 54% in China, according to Fang, et al. ⁷, whereas it was allowed in S2.

^c The cost of increasing the supply of food waste recycling service is modelled as a rising percentage of the initial cost of recycling food waste and food processing by-products as feed (54 dollar ton⁻¹), while the cost of decreasing the supply of food waste collection service is modelled as a declining percentage of the initial cost of collecting food waste and food processing by-products for landfill and incineration (82 dollar ton⁻¹). Economies of scale in food waste recycling were considered in S2, where a 1% increase in recycled waste resulted in only a 0.078% rise in recycling costs, indicating that increasing the amount of recycled waste might not necessarily incur additional costs, as reported by Cialani and Mortazavi ⁸. This is because, initially, recycling entails high fixed costs, yet as production scales up, marginal costs decrease and then stabilise. The total amounts of food waste and food processing by-products and their current use as animal feed and discarded biomass (i.e., landfill and incineration) for China in S0 were presented in Supplementary Tables 3. Physical quantities and prices of food waste recycling service and food waste collection service in China were presented in Supplementary Tables 4-5.

^d The main environmental problem associated with food systems depends on emissions from economic activities. Therefore, the introduction of economy-wide emission taxes could subsequently influence the way food is produced, inducing a shift away from emission-intensive production to cleaner alternatives. These policies aim to reduce emissions by pricing environmental emissions. Shadow prices of emissions, derived from the marginal value of the emission balance equations, ensure that total emissions by all producers remain below a specified emission threshold. For a given emission mitigation target for each type of pollutant, the AGE model can endogenously calculate the shadow prices of emissions of various pollutants.

Supplementary Table 2 | Physical quantities (Tg) in fresh form for each product in China (CN) and its main food and feed trading partners (MTP) in S0.

	CN	MTP
Cereal grains ^a	521.33	595.93
Oilseeds & pulses ^a	74.04	255.65
Vegetables & fruits ^a	397.23	116.39
Roots & tubers ^a	119.82	54.76
Sugar crops ^a	133.61	792.67
Other non-food crops ^a	36.48	23.24
Monogastric livestock ^a	103.15	18.65
Ruminant livestock ^a	52.53	46.28
Compound feed ^b	102.60	103.00
Cereal bran ^c	31.05	12.01
Alcoholic pulp ^c	45.60	76.09
Oil cake ^c	86.42	84.02
Processed food ^d	593.20	580.80
Nitrogen fertiliser	39.60	13.65
Phosphorous fertiliser	17.43	3.13
Grass ^e	286.22	0.00

^a Physical quantities of cereal grains, oilseeds & pulses, vegetables & fruits, roots & tubers, sugar crops, other non-food crops, monogastric livestock, ruminant livestock, nitrogen fertiliser, and phosphorous fertiliser were obtained from FAO ¹⁹. Here, physical quantities of cereal grains waste, oilseeds & pulses waste, vegetables & fruits waste, and roots & tubers waste were excluded and presented in Supplementary Table 3.

^b Compound feed production data was calculated according to the weighted averages of crops included in the compound feed at the national level.

^c Physical quantities of cereal bran, alcoholic pulp, and oil cake were estimated from the consumption of corresponding food products and specific technical conversion factors ²⁰.

^d Processed food was calculated according to the weighted averages of crops included in the processed food at the national level.

^e Grass from natural grassland was derived from Miao and Zhang ²¹. Here, grass refers to grass from natural grassland where ruminant livestock is grazing for feed, and grass from remaining grassland is excluded. We do not present grass production data in MTP due to data unavailability.

Supplementary Table 3 | Utilisation rates (%) of food waste and food processing by-products in the baseline (S0) for China.

	Used as feed (%)	Discarded biomass (%) ^c
Cereals waste	39% ^a	Landfill (40%) & incineration (21%)
Vegetables & fruits waste	39% ^a	Landfill (40%) & incineration (21%)
Roots & tubers waste	39% ^a	Landfill (40%) & incineration (21%)
Oil seeds & pulses waste	39% ^a	Landfill (40%) & incineration (21%)
Cereal bran	36% ^b	Landfill (42%) & incineration (22%)
Alcoholic pulp	16% ^b	Landfill (55%) & incineration (29%)
Oil cake	72% ^b	Landfill (18%) & incineration (10%)

^a In China, quantitative empirical data on food waste recycled as feed for monogastric livestock was not available. We infer that the practices of feeding food waste to monogastric livestock in Japan and South Korea are rather similar to those in China, following Fang, et al. ⁷. Thus, we assumed that a similar proportion (39%, the mean of values in Japan and South Korea ²²) of food waste was being used as feed in China in 2014 in S0.

^b The utilisation rates of food processing by-products recycled as feed in China in 2014 in S0 were based on Fang, et al. ⁷.

^c Excluding the portion of food waste and food processing by-products recycled as feed, 66% of the remaining amount in China in 2014 was sent to landfills, while 34% was incinerated, according to Kaza, et al. ²³ and Bhada-Tata and Hoornweg ²⁴.

Supplementary Table 4 | Physical quantities (Tg) of food waste and food processing by-products and their utilisation in China in S0.

	Total in fresh form (Tg)	Total in dry matter (Tg)	Total in crude protein (Tg)	Total in energy (billion MJ)	Physical quantity in fresh form (Tg)	
					Used as feed ^a	Discarded biomass ^b
Total food waste	226	54	7	690	88	138
1) Cereal grains waste ^b	36.09	31.40	3.14	447	14.08	22.02
2) Vegetables & fruits waste ^b	175.01	17.50	2.98	183	67.76	107.25
3) Roots & tubers waste ^b	13.32	3.46	0.28	42	5.20	8.13
4) Oilseeds & pulses waste ^b	1.28	1.19	0.18	18	0.50	0.78

3) Oil cake ^c	86.42	76.91	35.38	1130	59.80	26.59
Total	389	192	56	2597	166	223

^a The amount of food waste used as feed corresponds to the quantity directed to the “food waste recycling service” sector. The amount of food processing by-products used as feed are not directed to the “food waste recycling service” sector; instead, these by-products with economically values are purchased directly by livestock producers in the feed market. When upcycling the discarded biomass of food waste and food processing by-products, these biomass are directed to the “food waste recycling service” sector.

^b Discarded biomass of food waste and food processing by-products refers to the quantity collected for landfill and incineration, meaning the amount directed to the “food waste collection service” sector.

Supplementary Table 5 | Prices of food waste recycling service and food waste collection service in China. ^a

	Food waste treatment	Price ^b (dollar ton ⁻¹)	Weighted price ^c (dollar ton ⁻¹)
Food waste recycling service	Recycling waste as feed	54	54
	Collection	40	
Food waste collection service	Landfill	31	82
	Incineration	64	

^a Food waste recycling service refers to recycling food waste as feed for monogastric livestock production, and food waste collection service means collecting food waste for landfill and incineration.

^b The process of recycling food waste and food processing by-products as animal feed involves sorting, shredding, thermal treatment, fermentation, hydrolysis, and extrusion to create animal feed, as outlined by Alsaleh and Aleisa ²⁵. Collection includes pick up, transfer, and transport to final disposal site for food waste. By multiplying the quantity of food waste with the price of food waste treatment, we can calculate the value of food waste generation. The prices of food waste recycling service and food waste collection service are obtained from Alsaleh and Aleisa ²⁵, Kaza, et al. ²³ and Bhada-Tata and Hoornweg ²⁴. Since the value of food waste generation needs to be taken from the “wtr” demand of consumers and monogastric producers, we further checked whether or not the value of food waste generation is more than 80% of the initial demand of “wtr”. If it is higher than 80% of the “wtr” demand, the value of food waste generation is scaled down.

^c The weighted price of food waste collection service = collection price (40 \$/t) + 66%*landfill price (31\$/t)+34%*incineration price (64\$/t)=82\$/t.

Supplementary Table 6 | The economic and mass allocation of food processing main and by-products. ^a

	Main and by-products	By-product group	Economic share (%)	Mass share (%)
Cereal flour production ^a	Cereal flour	-	93%	86%
	Cereal bran	Cereal bran	7%	14%
Maize ethanol production ^b	Maize ethanol	-	83%	49%
	Distillers' grain from maize ethanol	Alcoholic pulp	17%	51%
Barley beer production ^b	Barley beer	-	98%	82%
	Brewers' grain from barley beer	Alcoholic pulp	2%	18%
Liquor production ^b	Liquor	-	97%	25%
	Distillers' grain from liquor	Alcoholic pulp	3%	75%
Vegetable oil production ^c	Soybean oil	-	44%	23%
	Soybean oil cake	Oil cake	56%	77%
	Other oil	-	66%	43%
	Other oil cake	Oil cake	34%	57%

Appendix Table 1 | Sectoral aggregation scheme.

Aggregated sectors	GTAP original sectors
Cereal grains	“Paddy rice (pdr)”, “Processed rice (pcr)”, “Wheat (wht)”, and “Cereals grains nec (gro)” sectors
Oilseeds & pulses	“Oil seeds (osd)” sector, and pulses split from the original “Vegetables& fruits (v_f)” sector
Vegetables & fruits	“Vegetables, fruits, nuts (v_f)” sector after splitting out pulses, and roots & tubers
Roots & tubers	Split from the original “Vegetables& fruits (v_f)” sector
Sugar crops	“Sugar cane & Sugar beet (c_b)” and Sugar (sgr)” sectors
Other non-food crops	“Plant-based fibers (pfb)”, and “Crops nec (ocr)” sectors
Monogastric livestock	“Animal products nec (oap)” and “Meat products nec (omt)” sectors
Ruminant livestock	“Cattle, sheep, goats, horses (ctl)”, “Meat: cattle, sheep, goats, horses (cmt)”, “Raw milk (rmk)”, “Wool, silk-worm cocoons (wol)”, and “Dairy products (mil)” sectors
Compound feed ^a	Split from the original “Food products nec (ofd)” sector
Cereal bran ^a	Split from the original “Food products nec (ofd)” sector
Alcoholic pulp ^a	Distiller’s grains from maize ethanol production split from the original “Food products nec (ofd)” sector; Distiller’s grains from liquor production and brewer’s grains from barley beer production split from the original “Beverages and Tobacco products (b_t)” sector
Oil cake ^a	Split from the original “Vegetable oils and fats (vol)” sector
Processed food ^a	“Food products nec (ofd)” sector after splitting out splitting out compound feed, cereal bran, and distiller's grains from maize ethanol production; “Beverages and Tobacco products (b_t)” sector after splitting out distiller’s grains from liquor production and brewer’s grains from barley beer production; Vegetable oils and fats (vol)” sector after splitting out oil cake
Nitrogen fertiliser ^b	Split from the original “Manufacture of chemicals and chemical products (chm)” sector
Phosphorous fertiliser ^b	Split from the original “Manufacture of chemicals and chemical products (chm)” sector
Food waste recycling service ^c	Split from the original “Waste and water (wtr)” sector

Aggregated sectors	GTAP original sectors
Food waste collection service ^c	Split from the original “Waste and water (wtr)” sector
Non-food	“Manufacture of chemicals and chemical products (chm)” sector after splitting out nitrogen fertiliser and phosphorous fertiliser; “Waste and water (wtr)” sector after splitting out food waste recycling service and food waste collection service; “Forestry (frs)”, “Fishing (fsh)”, “Coal (coa)”, “Oil (oil)”, “Gas (gas)”, “Minerals nec (oxt)”, “Petroleum, coal products (p_c)”, “Electricity (ely)”, “Gas manufacture, distribution (gdt)”, “Textiles (tex)”, “Wearing apparel (wap)”, “Leather products (lea)”, “Wood products (lum)”, “Paper products, publishing (ppp)”, “Manufacture of pharmaceuticals, medicinal chemical and botanical products (bph)”, “Manufacture of rubber and plastics products (rpp)”, “Mineral products nec (nmm)”, “Ferrous metal (i_s)”, “Metal nec (nfm)”, “Metal products (fmp)”, “Electronic equipment (ele)”, “Manufacture of electrical equipment (eeq)”, “Manufacture of machinery and equipment n.e.c. (ome)”, “Motor vehicles and parts (mvh)”, “Transport equipment nec (otn)”, “Manufactures nec (omf)”, “Construction (cns)”, “Wholesale and retail trade; repair of motor vehicles and motorcycles (trd)”, “Accommodation, Food and service activities (afs)”, “Land transport and transport via pipelines (otp)”, “Warehousing and support activities (whs)”, “Sea transport (wtp)”, “Air transport (atp)”, “Communication (cmn)”, “Financial services nec (ofi)”, “Insurance (ins)”, “Real estate activities (rsa)”, “Other Business Services nec (obs)”, “Recreation & other services (ros)”, “Other Services (Government) (osg)”, “Education (edu)”, “Human health and social work (hht)”, “Dwellings: ownership of dwellings (imputed rents of houses occupied by owners) (dwe)” sectors

^a Compound feed was split from the “Food products nec (ofd)” sector in the original GTAP database. The substance flow from “Food products nec (ofd)” to monogastric livestock and ruminant livestock was compound feed. Cereal bran and distiller’s grains from maize ethanol production were taken from the newly-split sector of compound feed according to the shares of economic values of cereal bran and distiller’s grains from maize ethanol production in the total economic value of compound feed. Economic values of cereal bran and distiller’s grains from maize ethanol production were calculated by multiplying the physical quantity (in tons) and the corresponding price (dollar per ton). Distiller’s grains from liquor production and brewer’s grains from barley beer production were split from the “Beverages and Tobacco products (b_t)” sector in the original GTAP database. The substance flow from “Beverages and Tobacco products (b_t)” to monogastric livestock were distillers' grains from liquor production and brewers' grains from barley beer production. Oil cake was split from the “Vegetable oils and fats (vol)” sector in the original GTAP database. The substance flow from the “Vegetable oils and fats (vol)” sector to monogastric livestock was oil cake.

^b The nitrogen and phosphorus fertilisers were taken from the original 'Manufacture of chemicals and chemical products' sector following the method of Sturm³⁶ and Bartelings, et al.³⁷.

^c Food waste recycling service and food waste collection service were split from the “Waste and water (“wtr”)” sector in the original GTAP database according to the shares of economic values of food waste recycling service and food waste collection service in the total economic value of “Waste and water (“wtr”)” sector. The economic values of food waste recycling service and food waste collection service were calculated by multiplying the physical quantity (in tons) and the corresponding

price (dollar per ton). Since the value of food waste generation needs to be taken from the 'wtr' demand of consumers and monogastric producers, we further checked whether or not the value of food waste generation is more than 80% of the initial demand of "wtr". If it is higher than 80% of the 'wtr' demand, the value of food waste generation are scaled down.

Appendix Table 4 | Emissions sources of greenhouse gases, acidification pollutants, and eutrophication pollutants across various sectors of the model. ^a

Sectors	Emissions of greenhouse gases (Tg CO ₂ equivalents)	Emissions of acidification pollutants (Tg NH ₃ equivalents)	Eutrophication pollutants (Tg N equivalents)
Crop	<ul style="list-style-type: none"> • Rice methane (CH₄) • Synthetic fertiliser and manure application (N₂O) 	<ul style="list-style-type: none"> • Synthetic fertiliser and manure application (NH₃) 	<ul style="list-style-type: none"> • Synthetic fertiliser and manure application (N and P losses)
Livestock	<ul style="list-style-type: none"> • Enteric fermentation (CH₄) • Manure management (CH₄ and N₂O) • Manure grassland (N₂O) 	<ul style="list-style-type: none"> • Manure management (NH₃) • Manure grassland (NH₃) 	<ul style="list-style-type: none"> • Manure management (N and P losses) • Manure grassland (N and P losses)
Non-agriculture	<ul style="list-style-type: none"> • Energy use (CO₂, CH₄, and N₂O) 	<ul style="list-style-type: none"> • Energy use (NH₃, NO_x and SO₂) 	<ul style="list-style-type: none"> • Energy use (N and P losses)

^a Emissions from the production of N and P fertilisers were attributed to the respective fertiliser sector, while emissions from the application of these fertilisers were assigned to the crop sectors to prevent double counting. Data on N and P fertiliser use by crop types and countries were derived from Ludemann, et al. ³⁹. Manure data by animals were derived from FAO ¹⁹. Allocation of manure for each crop was assumed to be consistent with the allocation of N fertiliser for each crop.
